Contents

Acknowledgments

This report would not have been possible without the assistance of:

- Midwives in Victoria who completed and returned the Perinatal Morbidity Statistics Forms
- Maternal and Child Health Nurses who completed and returned the Birth Defect Notification forms
- Health Information Managers
- Royal Children's Hospital—Health Information Management, Cardiology Unit, Orthopaedic Unit, Information Technology, Ron Burnett
- Royal Women's Hospital—Health Information Management, Ultrasound Department and Genetics Clinic
- Monash Medical Centre—Health Information Management, Ultrasound Department and Genetics Clinic, Information Technology, Ron Lees
- Victorian Clinical Genetics Service—Metabolic Clinic
- Dr Catherine Rose, Consultant Medical Officer, Perinatal Data Collection Unit
- Medical Practitioners who completed and returned the Birth Defect Notification forms
- Members of the Consultative Council on Obstetric and Paediatric Mortality and Morbidity
- Staff of the Perinatal Data Collection Unit
- Dr Agnes Bankier, Dr Robin Bell, Dr James King, Professor Judith Lumley and Mrs Christine Stone who all contributed to the final report

We thank all of the above people for their contributions.

Definitions

Livebirth is the complete expulsion or extraction from its mother of a baby of at least 20 weeks gestation or, if gestation is unknown, weighing at least 400 grams who, after being born, breathes or shows any evidence of life such as a heartbeat.

Birth defects are structural or anatomical abnormalities that are present at birth, usually resulting from abnormal development in the first trimester of pregnancy.

Birth defect cases refers to the number of liveborn or stillborn infants affected by at least one birth defect.

Neonatal death refers to a death occurring within 28 days of livebirth in an infant whose gestation was at least 20 weeks or, if gestation is unknown, weighing at least 400 grams.

Perinatal death is a stillbirth or neonatal death.

Stillbirth is the complete expulsion or extraction from its mother of a baby of at least 20 weeks gestation or, if the gestation is unknown, weighing at least 400 grams. who did not, at any time after delivery, breathe or show any evidence of life such as a heartbeat.

Termination of pregnancy in this report, refers to an induced abortion by medical or mechanical means before 20 weeks gestation.

Birth prevalence has as the numerator, the number of still and livebirths at and after 20 weeks gestation. **Overall prevalence** includes terminations of malformations before 20 weeks gestation.

List of Figures

List of Tables

Highlights

- In the 16 year study period, 1983 to 1998, there have been 32,445 babies born with a birth defect at or after 20 weeks gestation. Another 2,402 were identified as terminations of pregnancy before 20 weeks gestation. This gives an overall prevalence of 344 / 10,000 or 3.4%. From 1995–1998 the overall prevalence was 388 / 10,000 or 3.9%
- The four most common defects for the period 1995–1998 are hypospadias, ventricular septal defect, congenital dislocation of the hip and obstructive defects of the renal pelvis.
- For the first time in 1998 there was a substantial decline in both anencephaly and spina bifida. This may be a chance fluctuation or it may indicate effective nutritional intake of periconceptional folate. The overall prevalence of these birth defects in pregnancy is 1 / 1,724 for anencephaly, 1 / 1,190 for spina bifida or 1 / 704 for either neural tube defect. There are now less than 15 babies per year liveborn with spina bifida.
- Advanced maternal age is significantly associated with hydrocephalus, exomphalos, Down syndrome and other chromosome abnormalities.
- Teenage mothers have a significantly increased risk of having babies with spina bifida, hydrocephalus and gastroschisis.
- There are some significant gender differences in birth prevalence with males at higher risk compared with females. Birth defects significantly associated with males include cardiac (transposition of great vessels, Tetralogy of Fallot, coarctation of aorta) or renal (anorectal atresia, renal agenesis / dysgenesis, obstructive defects of renal pelvis). Males are also at increased risk of cleft lip and palate and Down syndrome, while females have an increased risk for anencephaly, cleft palate and congenital dislocation of the hip.
- Congenital dislocation of the hip is a very common birth defect, reported in 28.6 / 10,000 births or 1 / 350 births (1983–1998), with female babies having a fourfold increased risk for this condition over male babies.
- The number of cases reported with obstructive defects of the renal pelvis continues to increase annually. This is due to increased reporting secondary to ultrasound detection in pregnancy.
- The number of babies living beyond 28 days with hypoplastic left heart and diaphragmatic hernia has not increased. There has been an improved survival rate for babies with renal agenesis / dysgenesis with 55% between 1995–1998 surviving beyond 28 days compared with only 33% in 1983–1994.
- The overall prevalence of Down syndrome has increased, due to there being a larger number of older women becoming pregnant. At the same time, the proportion of fetuses with Down syndrome that are detected in pregnancy has markedly increased. There are now approximately 65 liveborn babies with Down syndrome each year in Victoria.
- The proportion of all babies with Down syndrome born to women less than 35 years has decreased so that in 1995–1998 it was 44%, not over 60% as in earlier years. This shift in proportions is probably due to affected fetuses, that would once have spontaneously aborted and never been identified as affected, now being identified by prenatal testing in older women in the first and early second trimester.
- A number of birth defects are associated with a high frequency of chromosome abnormalities: e.g. Tetralogy of Fallot (14%) and exomphalos (26%). Overall , 6.7% of birth defects have a chromosomal abnormality which represents 0.4% of all pregnancies.
- The prevalence of having a baby affected by a birth defect increases with increasing age. Women aged 35 years or more, 11.7% of all mothers for the period 1983–1998, comprise 15% of all mothers who have a pregnancy affected by a birth defect for this same period. They have a relative risk of having a baby with a birth defect of 1.34 (1.3–1.38) compared with younger women. If the chromosomal abnormalities—Down Sydrome, Patau Syndrome and Edward Syndrome—are excluded, the relative risk for women aged 35 years or more having a baby with a birth defect decreases to 1.13 (1.10–1.17).
- Women from the Middle East are significantly more likely to have a baby with a birth defect than women from any of the other country of birth groups. This is not related to advanced maternal age and may reflect genetic factors.

- Women from Rural Regions (grouped) have a statistically significant decreased likelihood of having a baby with a birth defect when compared to Metropolitan Regions (grouped) (RR 0.9, 96% CI 0.88–0.92, $p<0.0001$). This is a small decrease and may relate to ascertainment issues as much as a biological risk, such as the fact that they are generally younger than Metropolitan mothers.
- The prevalence of birth defects in pregnancies of women identified as Koori in the Perinatal Morbidity Statistics System is significantly less than for those identified as non-Koori (RR 0.77, 95% CI 0.66–0.91, $p=0.001$).
- Babies from multiple births are more likely to have a birth defect than babies from singleton births (RR 1.55, 98% CI 1.48–1.64, $p<0.0001$).

1. Introduction

1.1 Background

With the decline of mortality and morbidity in children from other causes (eg infection), birth defects are now more prominent as a serious health hazard of childhood. Almost 4% of Victorian babies are born each year with a malformation and they contribute substantially to the amount of perinatal mortality and morbidity.

In 1979 the Commonwealth Government agreed in principle to collect more information about births and malformations. It was decided that the States would be responsible for setting up their own systems and the Commonwealth would establish a National Perinatal Statistics Unit, to collate information from all the states and provide an overall picture. The Victorian Perinatal Data Collection Unit (PDCU) was established under the Health Act of 1982, and operates under the aegis of the Consultative Council on Obstetric and Paediatric Mortality and Morbidity (the Council). Under this same Health Act, 1982, one of the fundamental purposes for the establishment of the PDCU was the formation of a Birth Defects / Congenital Malformations Register (BDR).

This report presents a 16 year overview of key maternal and infant factors associated with birth defects. In many instances the data for the past 4 years are presented separately to highlight changes that have occurred over time. This report provides supplementary information to our previous report, *Congenital Malformations in Victoria 1983–1994 (1)*. Differences in prevalence data for some birth defects are often influenced by the inclusion of pregnancy termination data in this most recent report.

1.2 Purposes

The Victorian Birth Defects / Congenital Malformations Register is a state-wide population based surveillance system established to:

1. determine how often birth defects are occurring in Victoria and identify changing health service needs (prevalence and survival data),
2. give statistical information to organisations responsible for planning and providing health care facilities for those with birth defects, or who provide information to those concerned about having a baby with a birth defect,
3. provide information for epidemiological research to increase knowledge of aetiology and preventability of birth defects,
4. assess effectiveness of primary prevention and screening for birth defects,
5. respond to community concerns about perceived clusters or changes in frequency of birth defects.

The BDR was established in 1984 and collects information on all infants born in Victoria since 1982.

1.3 Inclusion Criteria

Notifiable malformations are defined, for Victorian data purposes, as structural defects or chromosomal abnormalities present at birth. We also collect information on inborn errors in metabolism, haematological disorders, congenital infections, neoplasms, and developmental delay. There are certain isolated minor malformations (such as inguinal hernia, and hydrocele) that are not notifiable and these are listed in Appendix. A.

The BDR collects data on all birth defects for livebirths, stillbirths and terminations of pregnancy occurring since January 1, 1982, irrespective of the age at diagnosis.

For the purposes of this report, information is included on all cases notified to the BDR **by December 31, 1999**. However, certain isolated minor defects, such as undescended testes (>=37 weeks gestation) and vesico-ureteric reflux, which are reported in the BDR, have been excluded

from this report. This is consistent with the reporting of birth defects in Congenital Malformations in Australia (2), but differs from reports from other state birth defect registries, where higher birth defect prevalence rates include such minor malformations.

Differences with the Annual Report (s) of the Consultative Council on Obstetric and Paediatric Mortality and Morbidity (3) and Congenital Malformations in Victoria, 1983–1994 (1)

Many differences in prevalence data exists between this current report and the Annual Report(s) of the Consultative Council on Obstetric and Paediatric Mortality and Morbidity and *Congenital Malformations in Victoria, 1983–1994 (1)*. This can primarily be attributed to the time period being reported in each report. The BDR continues to include data on children who are reported with a birth defect up until the age of 15 years. Therefore new cases are being added (or sometimes deleted) each year. Each report is current at the time of publication, but is never "complete".

There number of birth defects included in this report is approximately 300 less than that reported in the 1998 Council Annual Report (3) due to the exclusion of all cases with isolated undescended testes greater than 36 weeks gestation and vesicoureteric reflux.

Differences with AIHW NPSU Report , Congenital Malformations Australia (2)

There are considerable differences between the Victorian data contained in the Australian Institute of Health & Welfare (AIHW) National Perinatal Statistics Unit (NPSU) Report and the data presented here. These differences reflect both different inclusion criteria and variations in coding practice. We believe this report more accurately reflects the birth prevalence of birth defects in the State of Victoria.

1.4 Sources of Notification

The BDR is a voluntary notification system. Data are obtained from multiple sources. Table 1.1 details the number of notifications of birth defect cases for 1989–1998 births. The number of notifications exceeds the number of cases due to multiple reporting of cases from different sources.

Data on sources of notification have been maintained only since 1989. For the period 1989–1998 there were 40,524 notifications for a total of 24,316 cases. This approximates to 1.7 notifications per case.

Table 1.1 Sources of Notification, 1989–1998

Notification Source	Number	Percent(%)
PDCU—perinatal forms	16,391	40.4
Perinatal Death Certificate	1,968	4.9
Autopsy Report	1,266	3.1
Cytogenetics Report	2,369	5.8
Maternal and Child Health Nurse	3,584	8.8
Hospital listings	14,593	36.0
Other Professionals	290	0.7
Other (e.g. parent)	23	0.1
Unknown	40	0.1
Total	**40,524**	**100.0**

The Annual Report of the Consultative Council on Obstetric and Paediatric Mortality and Morbidity tabulates these figures and has recorded the changing proportion of notifications from these sources over the years. The latest Report (3) demonstrates that 58% of notifications were from the perinatal form, completed by midwives for every baby born in Victoria and sent to the PDCU.

1.5 Data Items

The BDR collects maternal, infant and fetal demographic data on all cases. All notifications (excluding terminations of pregnancy pre 20 weeks and interstate births) are linked to the Perinatal Morbidity Statistics Form to obtain a complete obstetric history for each case. The data items routinely maintained on the BDR are listed in Appendix B. Further data items are available for each case of 20 weeks or more from the PDCU where all the information from the Perinatal Morbidity Statistics Form is recorded.

1.6 Data Quality

Because of the voluntary nature of the BDR, it has been necessary to assess data quality by validation studies (4,5). The first, conducted in 1986, discovered that the proportion of birth defects notified to the BDR improved from 35% to 48% during the period 1982–1985. The second study, conducted in 1993, also reported a marked improvement in notification rates from 50% to 86% during the period 1989–1992.

Since 1992 considerable time and effort has been expended in improving the quality of the data in the BDR. The Register has been updated from hospital inpatient listings from the Royal Children's Hospital (RCH) detailing all children born since 1982 who have subsequently been admitted to RCH with a birth defect. We have also obtained listings of all children born since 1982 who have visited the RCH Cardiology Unit and the Victorian Clinical Genetics Service (VCGS) Metabolic Clinic, either as an inpatient or outpatient. This procedure has also been adopted for Monash Medical Centre where the inpatient listings date back to 1992.

1.7 Explanatory Notes

Cases verses Defects

Section 2 describes each *individual malformation*. Sections 4 & 5 describe birth defect cases—the number of liveborn or stillborn infants affected by at least one birth defect. Thus, the number of birth defects exceeds the number of cases.

Classification of Diseases

Conditions have been classified using the British Paediatric Association Classification of Diseases—Perinatal Supplement, compatible with International Classification of Diseases—9th revision.

With *Syndromes* it is the policy of the PDCU to code the syndrome **and** all of its manifestations.

Births and Confinements

There is an important difference between the number of births and the number of confinements (sometimes referred to as 'maternities'). Confinement is defined as the final phase of pregnancy during which labour and birth occur. Any one confinement can result in more than one birth, such as is the case with twins. Tables related to infant characteristics use births as the denominator. Tables related to maternal factors use confinements as the denominator. This differs from the previous report (1) where only births were used as the denominator for both infant and maternal characteristics.

Maternal Country of Birth

For the purposes of this report we have separated women born in Asia from those born in the Middle East. In the previous report (1) these women were combined in one category called "Asia including Middle East".

1.8 Terminations of Pregnancy

In this report termination of pregnancy refers to an induced abortion by medical or surgical means before 20 weeks gestation. If there is an induced abortion at 20 weeks or more, or if the gestation is unknown and the birthweight is 400 grams or more, it is required to be registered as a birth and is classified as a stillbirth by the PDCU and the BDR.

Notification of terminations for malformations only began in 1986. While the capture of these data in the early years was very incomplete, each subsequent year has shown a marked improvement in ascertainment of cases. There has also been an increase in the number of terminations because of the increased use of prenatal diagnosis.

Since 1986 a PDCU staff member has been responsible for reviewing the medical records of all patients with a termination for malformations at both Monash Medical Centre and the Royal Women's Hospital. A letter is sent to all other hospitals with maternity services to obtain information on patients who have had a termination for a malformation This procedure has an ICD code which enables extraction of these specific records.

This report differs from the previous report (1), because data on terminations for malformations have been included for all variables except birthweight. This was felt to be appropriate due to the improved data quality, and the importance of providing a complete picture of the prevalence of certain congenital defects where a high proportion of affected pregnancies are terminated.

1.9 Statistics

For each rate figure , a 95% Poisson confidence interval (if number of cases < 400) or a 95% Binomial confidence interval (if number of cases >= 400) has been calculated. This allows for comparisons between rates to be made and significant differences to be recognised; if the confidence intervals do not overlap, then the rates will be significantly different at the 5% level ($p < 0.05$). P values have not been estimated. Relative risks in sections 4 and 5 have been calculated using Epi Info Version 6.1.

1.10 Regional Variations

Victoria is divided into a number of Health Regions for planning and policy purposes. Between 1983–1998 changes have occurred in regional boundaries three times. Therefore, to provide regional trend data over this time necessitates allocation of certain postcodes to specific regions where regional and / or local government area (LGA) boundaries have changed.

For the purposes of this report, all postcodes from 1983 to 1998 have been assigned to current (1998) regional boundaries. This changes the proportion of births in each Region from the 1992–1995 boundaries in the following way: Barwon nil, Grampians +0.5%, Loddon Mallee +0.5%, Hume -0.2%, Gippsland nil, Western Metro -2.3%, Northern Metro + 1.5%, Eastern Metro +1.1%, Southern Metro -1.1%.

An example of how the re-distribution of postcodes can affect the proportion of cases in each Region between 1992–1995 and 1998, is tabulated below using spina bifida as an example.

Table 1.2: An Example: a Proportion of Spina Bifida Cases in Health Regions, 1992–1995 and 1998

Region	1992–1995 (%)	1998(%)
Barwon S W	6.0	5.7
Grampians	3.6	3.5
Loddon Mallee	6.6	7.0
Hume	5.6	5.5
Gippsland	6.6	6.8
Western Metro	17.1	15.2
Northern Metro	15.6	17.0
Eastern Metro	14.3	14.8
Southern Metro	23.0	22.7
Other	1.6	1.6

It should also be noted that the reassignment of postcodes from 1983–1996 to the current regional boundaries is only an approximation. In reality some postcodes are divided between two or more Regions in proportions ranging from 10% to 99%. In this report, postcodes between 1983–1996 have been allocated exclusively to one Region (see Appendix D.) Postcodes for 1997 and 1998 are correctly proportionately assigned to Regions as this is achieved during the creation of the Perinatal Morbidity Statistics file. *Any conclusions drawn from differences in the prevalence of malformations between Regions should be made with due consideration of the Regional boundary changes and allocation of postcodes.*

2. Summary Tables

2.1 Birth Defects by Year, 1983–1998

The combined birth prevalence of birth defects over 16 years is 344.2 / 10,000 or 3.4%. The increase until 1990 probably reflects improving ascertainment, but the fluctuations since 1990 are more likely to reflect "true prevalence", as the methods of ascertainment since then have been the same. From 1995–1998 the overall prevalence was 388 / 10,000 or 3.8%

Table 2.1 Birth Defects by Year, 1983–1998

Year	Total Births 20 Weeks and Later	Defects, 20 Weeks and Later	Defects Before 20 Weeks (Terminations)	N/10,000 Pregnancies (including Terminations)	%
1983	60,628	1,700	2	280.7	2.8
1984	60,737	1,746	11	289.3	2.9
1985	61,189	1,622	18	268.0	2.7
1986	61,253	1,634	83	280.3	2.8
1987	61,566	1,657	60	279.7	2.8
1988	63,666	1,889	109	313.8	3.1
1989	64,255	2,023	126	334.4	3.3
1990	66,878	2,269	143	360.7	3.6
1991	65,248	2,332	142	379.2	3.8
1992	66,305	2,382	157	382.9	3.8
1993	64,737	2,255	207	380.3	3.8

Limb Reduction Defects	461	6.0	181	7.2
Diaphragmatic Hernia	253	3.3	104	4.1
Exomphalos	218	2.9	97	3.8
Gastroschisis	100	1.3	65	2.6
Trisomy 21	1,195	15.7	525	20.8
Trisomy 13	108	1.4	62	2.5
Trisomy 18	266	3.5	156	6.2

2.3 Order of Prevalence of Twenty Seven Selected Birth Defects, 1995–1998

The following table shows the order of prevalence of twenty-seven selected defects presented in section three of this report for 1995–1998. These are the defects adopted by the International Clearinghouse for Birth Defects Monitoring System and are those reported by the National Perinatal Statistics Unit (2). The three most common defects for this period were hypospadias, ventricular septal defect and obstructive defects of the renal pelvis.

Table 2.3 Order of Prevalence of Twenty Seven Selected Birth Defects, 1995–1998

Anomaly	N/10,000	1 in x Number of Births
Hypospadias	32.1	312
Ventricular Septal Defect	29.1	344
Obstructive Defects of the Renal Pelvis	28.0	357
Congenital Dislocation of Hip	26.1	383
Trisomy 21	20.8	481
Hydrocephalus	8.9	1,124
Spina Bifida	8.1	1,235
Cleft Palate	7.8	1,282
Anencephaly	7.3	1,370
Limb Reduction Defects	7.2	1,389
Cystic Kidney	6.6	1,515
Renal Agenesis and Dysgenesis	6.5	1,538
Cleft Lip and Palate	6.2	1,613
Trisomy 18	6.2	1,613
Anorectal Atresia and/or Stenosis	5.4	1,852
Transposition of Great Vessels	5.3	1,887
Oesophageal Atresia and/or Stenosis	4.1	2,439
Diaphragmatic Hernia	4.1	2,439
Coarctation of Aorta	4.0	2,500
Tetralogy of Fallot	3.8	2,632
Exomphalos	3.8	2,632
Cleft Lip	3.3	3,030
Microcephalus	2.7	3,704
Gastroschisis	2.6	3,846
Hypoplastic Left Heart Syndrome	2.5	4,000
Trisomy 13	2.5	4,000
Encephalocele	1.5	6,667

2.4 Summary of Patterns of Birth Defects, 1983–1998

The table below reflects the associations with other birth defects for twenty-four selected defects: that is, whether they are isolated conditions, or associated with chromsomal anomalies or occur as multiple same system (eg. two or more cardiac defects) or multiple system defects (eg. cleft lip and ventricular septal defect).

Table 2.4 Summary of Patterns of Birth Defects, 1983–1998

Anomaly	Total	% Isolated	% Chromosomal	% Other (Multiple Same System & Multiple Different Systems, Multiple NTD)
Anencephaly	586	72.7	1.2	26.1
Spina Bifida	854	63.2	3.5	33.3
Encephalocele	187	45.5	2.7	51.0
Microcephalus	310	29.4	14.2	56.4
Hydrocephalus	721	42.7	12.2	45.1
Transposition of Great Vessels	506	9.1	5.5	85.4
Tetralogy of Fallot	353	21.3	13.9	65.0
Ventricular Septal Defect	2,783	37.4	14.7	47.9
Hypoplastic Left Heart Syndrome	268	36.6	10.8	52.6
Coarctation of Aorta	548	17.9	8.2	74.0
Cleft Palate	748	59.0	9.0	32.0
Cleft Lip	380	85.0	3.4	11.6
Cleft Lip & Palate	662	68.1	11.3	20.5
Oesophageal Atresia and/or Stenosis	377	35.8	11.9	52.3
Anorectal Atresia and/or Stenosis	427	31.6	7.3	61.2
Hypospadias	2,657	86.4	1.4	12.3
Renal Agenesis/Dysgenesis	533	31.1	6.0	16.9
Cystic Kidney	469	38.2	7.5	54.3
Obstructive Defects Renal Pelvis	1,545	61.5	5.1	33.4
Congenital Dislocation of Hip	2,902	92.5	0.8	6.7
Limb Reduction Defects	642	40.8	8.7	50.4
Diaphragmatic Hernia	357	48.5	9.0	42.6
Exomphalos	315	27.0	25.7	47.3
Gastroschisis	165	67.3	1.8	30.4

2.5 Birth Defects by Major Anatomical System, Victoria, 1983–1998

The following figures refer to individual birth defects, not cases. The order of the birth defects reflects that determined by the coding system.

Table 2.5 Birth Defects by Major Anatomical Site, 1983–1998

Codes	Defects	Number	% of All Birth Defects	N/10,000 Pregnancies
Total		**55,743**		
740-2	Nervous System	4,519	8.1	44.5
743	Eye	814	1.5	8.0
744	Ear, Face & Neck	1,081	1.9	10.7
745-6	Heart	9,595	17.2	94.5
747	Circulatory System	4,348	7.8	42.8
748	Respiratory System	1,584	2.8	15.6
749	Cleft Palate/Lip	1,810	3.2	17.8
750-1	Digestive System	3,475	6.2	34.2
752	Genital Organs	3,992	7.2	39.3
753	Urinary System	3,928	7.0	38.7
755	Limbs	3,711	6.7	36.6
754/6	Other Musculoskeletal	8,563	15.4	84.4
757	Integument	467	0.8	4.6
758	Chromosomal	3,746	6.7	36.9
759	Other & Unspecified	1,289	2.3	12.7
760	Maternal Conditions	9	0.0	0.1
7710-2	Congenital Infections	87	0.2	0.9

2.7 Indications for Terminations of Pregnancy for a Birth Defect Before 20 weeks Gestation, 1989–1998

Between 1989–1998 there were 2,119 terminations of pregnancy for birth defects before 20 weeks reported to the BDR. Of these cases, almost 50% of pregnancies were terminated for a chromosomal anomaly and another 24% for Central Nervous System Defects (mainly Anencephaly or Spina Bifida).

Anencephaly

British Paediatric Association code 740.02

Total or partial absence of the cranial vault, the covering skin and the brain tissue.

- By 1989 the number of terminations of pregnancy exceeded the number of stillbirths and neonatal deaths, due to the relative ease with which this malformation is detected *in utero* by ultrasound. Before 1992 information about terminations was not readily available and the numbers presented for the earlier time period are almost certainly an underestimate of the true overall prevalence. Between 1995 and 1998, 75% of fetuses with anencephaly were detected during pregnancy and followed by a termination. `
- The number of births reported to the BDR (including terminations) has shown annual fluctuations with no evidence of a significant decline in the actual number of affected pregnancies. An increase was observed in 1995 and a substantial decline in 1998. This decline (which includes terminations) may reflect greater nutritional intake of periconceptional folate and thus a reduction in incidence of neural tube defects. There was also a decline in apparent incidence of spina bifida in 1998 (see Figure 3.2). These data will be monitored carefully to ensure they do not represent a chance fluctuation.
- Almost two-thirds of babies with anencephaly are female, a statistically significant difference from the sex ratio in all births.
- Five percent of anencephalic babies are one of a twin. A slight decline in twin pregnancies associated with anencephaly was observed in 1995–1998 (4.9% compared with 5.2%). The birth prevalence amongst twins, 11.5 / 10,000, is twice that amongst singletons, 5.6 / 10,000, and this difference is significant.
- The decrease in proportion of babies born with birth weight >2,500 gm in 1995–1998 is due to the increased proportion of pregnancy terminations.
- There are no significant associations of anencephaly with the maternal characteristics, age country of birth and region of residence.

Spina Bifida

British Paediatric Association code 741.00–741.99

Non-closure of the spine resulting in herniation or exposure of the spinal cord and/or meninges. Hydrocephalus may or may not be present.

- This is a more common neural tube malformation than anencephaly. There have been 854 reported in the 16 year period (8.4 /10,000) compared with 586 anencephaly (5.8 /10,000). This may reflect ascertainment differences in the 1980s when information on pregnancy terminations associated with anencephaly was often missing. In more recent years, the prevalence was similar—7.3/10.000 for anencephaly and 8.1/10,000 for spina bifida.
- Until 1998, there had been no marked change in the annual number of babies with spina bifida, with fluctuations of between 50 to 60 per year (approximately 1/1,200). However, there has been a significant increase in the number that are detected *in utero* and a subsequent decline in the number of livebirths (less than 20 per year). In 1998 there was a substantial drop in prevalence and incidence (as indicated by the decline in terminations of pregnancies). As with anencephaly, this may be a chance fluctuation or it may indicate effective use of periconceptional folate.
- Since 1993 the number of terminations has exceeded the number of births
- Amongst babies with spina bifida, 33% survived the neonatal period, 48% were stillborn or terminations and 19% died within 28 days. The proportion of babies surviving beyond 28 days has decreased from 36% in 1983–1994 to 23% in 1995–1998.
- There is a non-significant excess of females and twin gestations.
- There is an inverse linear trend with maternal age with women in younger age groups at greater risk than older women, and with teenagers having a particularly high risk. However, from 1995–1998, there were fewer births to teenage mothers and more to older mothers than in the earlier years.
- This neural tube defect is not as common in births to Asian-born women and the prevalence is significantly different from that of several other ethnic groups, including Australian-born women.
- There is a significantly lower birth prevalence in Eastern Metro region compared with Gippsland, Western and Southern Metro regions.

Encephalocele

British Paediatric Association code 742.00–742.09

Cystic expansion (herniation) of meninges and brain tissue outside the cranium, covered by normal or atrophic skin

- This is the rarest of the neural tube defects with only 14 cases reported from 1995–1998 and an overall prevalence of 1.8 / 10,000. The decline in overall prevalence that was observed for other neural tube defects was also observed for encephalocele in 1998.
- Fluctuations in reported number of cases are seen, with 1994 having the highest number.
- Many babies are stillborn or die in the newborn period, this malformation often being associated with others.
- There is a non-significant excess of females.
- As with anencephaly, this neural tube defect is present in twin babies twice as often as amongst all births. However, the numbers are small and this is not a significant difference.
- There is no association with maternal age
- There is a borderline significant two-fold increased risk of encephalocele in the Asian-born women, compared with Australian-born women, especially apparent in the last four year period.
- Regional variations exist but the only significant difference is that Western Metro has significantly more babies born with this neural tube defect compared with Southern Metro.

Microcephalus

British Paediatric Association code 742.19

Reduction in the size of the brain, with head circumference less than three standard deviations below the mean measurement for the same gestation or age. There are multiple known and unknown causes of microcephaly and it therefore cannot be considered as a single condition.

- The significant decline in the overall prevalence of microcephaly in the 12 year study period to 1994 (χ^2 for linear trend = 11.71, $p < 0.001$) did not continue in 1995. In that year there was a large increase, but since then, the numbers have remained stable. This demonstrates clearly the marked annual fluctuations that are sometimes observed. We do not know whether there may have existed some contributing unidentified causal agent that year or whether this was just a chance fluctuation.

  The original decline is thought to be the result of reporting inconsistencies—in the earlier years absolute microcephaly may have been reported to the BDR i.e. head circumference below the third standard deviation from the mean, no matter whether the baby was also of low birth weight (due to IUGR or prematurity). Such practice has changed, with relative microcephaly being the usual criterion for reporting in more recent years.

- There are almost no terminations of pregnancy reported for this condition.
- Babies with microcephaly are seldom stillborn (9%), and the neonatal death rate has dropped from 24% to 16%.
- There is a non-significant female excess .
- There is no significant maternal age effect.
- There is an increased risk for women of Middle Eastern background, compared with Australian-born women.
- There are no significant regional differences in birth prevalence.

Hydrocephalus

British Paediatric Association code 742.30–742.39

Dilatation of the ventricular system, not due to primary atrophy of brain and not necessarily associated with enlargement of the skull. These cases exclude hydrocephalus associated with spina bifida.

- There has been an increase in reported numbers since 1990, from 30–35 per year to around 50 per year.

  This increase reflected better ascertainment when new technologies enabled recognition of dilated ventricles otherwise missed.
  - Mild cases of hydrocephaly are diagnosed by CAT scanning which is used more frequently than in the early and mid 1980s. Then it was used only when there was a strong indication to do so.
  - Affected fetuses are being diagnosed prenatally by routine ultrasound leading to an increased number of pregnancy terminations. There has been no increase in prenatal detection and pregnancy termination in the last study period.
- There is a high stillbirth rate of 25% and another 20% of pregnancies are terminated before 20 weeks. There are about 20 babies surviving the neonatal period (39%) each year.
- There is a non-significant excess of males with hydrocephalus.
- This malformation is overrepresented in twin pregnancies, being found in 6% of cases.
- There is a strong U-shaped association with maternal age: a significant increased risk for teenage women and those over 40 years of age, compared to women of all other ages.
- There are no significant associations with maternal country of birth nor region of residence.

Transposition of Great Vessels

British Paediatric Association code 745.10–745.19

Maldivision of the arterial truncus causes the aorta to emerge from the right ventricle and the pulmonary truncus from the left ventricle.

- The relatively high overall prevalence rate (compared with the Australian data ref: Congenital Malformations Australia, 1995 and 1996(3) of 5.0/10,000 probably reflects good ascertainment in Victoria, due primarily to our receiving the cardiology inpatient listings from the Royal Childrens Hospital.
- There has been a decline in birth prevalence in the last five years, despite no pregnancy terminations less than 20 weeks for this malformation since 1996. There has however been an increase in the number of stillbirths in this period.
- Almost 80% survive the neonatal period—this is not a lethal malformation if a successful operation is performed.
- There is a significant excess of males with this condition.
- There are no significant associations with mother's age, country of birth nor region of residence.

Tetralogy of Fallot

British Paediatric Association code 745.20

An anomaly of the heart consisting of pulmonary stenosis, interventricular septal defect, dextraposed aorta that receives blood from both ventricles and hypertrophy of the right ventricle.

- The overall birth prevalence before 1990 was generally lower than in later years, but this may reflect the method of reporting only. This condition used to be reported as VSD plus pulmonary stenosis or atresia and was not necessarily called Tetralogy of Fallot. Reporting changed in about 1990 at the Royal Children's Hospital so that nomenclature of cases included Tetralogy of Fallot. There is continuing lower overall prevalence of Tetralogy of Fallot (3.5 / 10,000) compared with Transposition of the Great Arteries (5.0 / 10,000).
- There has been a slight decline in the proportion of cases that survive the neonatal period: 90% in 1983–94 to 82% in 1995–98. This is associated with an increase in the proportion of terminations of pregnancy and stillbirths in the presence of this condition.
- There is a significant excess of males with this condition.
- There is no significant linear trend with advancing maternal age.
- Women born in Asia have a significantly greater risk of having a baby with this condition compared to Australian-born women.
- There are no significant regional associations.

Ventricular Septal Defect

British Paediatric Association code 745.40–745.49

A defect in the septum between the left and right ventricles of the heart, which permits blood to be shunted between them.

- This is a one of the most common defects reported and is seen with other cardiac malformations in 32% of cases and as an isolated abnormality in 37% of cases.
- There was an increased overall prevalence recorded up to 1994, but in the last four years there has been a decline. There are now over 160 cases per year and a prevalence of 29.1 / 10,000 births in the last four years.
- This defect is not often associated with death in the perinatal period.
- There is a non-significant linear trend with advancing maternal age. The relatively high frequency of this malformation in babies born to women 40 years and over may be related to the association of this malformation with Down syndrome and other chromosomal disorders.
- There are significantly more babies with VSD born to women of Middle Eastern origin compared to Australian-born women, but no other significant associations with mother's country of birth nor region of residence.

Hypoplastic Left Heart Syndrome

British Paediatric Association code 746.79

Severely underdeveloped left side of the heart as a result of aortic valve atresia, mitral valve atresia, or a combination of both.

- There has been no change in overall prevalence with numbers fluctuating each year.
- This has a lower prevalence than the other major cardiac malformations (2.6/10,000), but is considerably more likely to be lethal, with 62% dying in the newborn period. Neonatal death rates were higher in 1983–1994 than in 1995–1998, but the proportion surviving beyond 28 days has not increased substantially. The proportion of terminations has increased.
- There is no significant difference in the prevalence of this defect in male and female babies.
- There is no significant association with maternal age, country of birth nor region of residence. The increased prevalence in babies born to Middle Eastern women and to women living in Hume region is not significant.

Coarctation of Aorta

British Paediatric Association code 747.10–747.19

Narrowing of the aorta, either distal or proximal to the ductus arteriosus

- This cardiac malformation is twice as prevalent as Hypoplastic Left Heart syndrome and Tetralogy of Fallot, with a slight decline in prevalence in the last few years. It is often associated with other cardiac defects (58%).
- There is little association with neonatal death, 86% surviving this period.
- There is a significant excess in male babies.
- There is no association with maternal age.
- There is a significantly reduced prevalence in babies born to Asian-born women compared to Australian-born women.
- There are no significant associations with region of residence.

Cleft Palate

British Paediatric Association code 749.00 – 749.09

Fissure defect of the hard and / or soft palate usually positioned in the mid-line, but without clefting of the lips. This is considered to be a distinct malformation, with different aetiology from cleft lip and palate together (see next section).

- The numbers of babies with cleft palate have fluctuated over the years, with no significant change in birth prevalence over the 16-year period (7.3 / 10,000 in 1983–94 and 7.8 / 10,000 in 1995–98).
- This is often associated with other malformations and thus the occurrence of terminations, stillbirths and neonatal deaths in 13% of cases.
- There is a significant excess of female babies with this condition.
- There is no significant association with maternal age, maternal country of birth nor region of residence.

Cleft Lip

British Paediatric Association code 749.10–749.19

Clefting of the upper lip, without clefting of the alveolar ridge and palate.

- Numbers have fluctuated each year with an overall prevalence of 3.8/10,000, or almost half as prevalent as cleft palate.
- This is an isolated birth defect in 85% of cases.
- Isolated cleft lip is not associated with stillbirth nor neonatal death as often as cleft palate.
- There are no significant associations with gender, maternal age, maternal country of birth, nor region of residence.

Cleft Lip and Palate

British Paediatric Association code 749.20–749.29

Clefting of the upper lip, with clefting of the alveolar ridge and palate.

- The numbers are fluctuating each year, with an overall prevalence of 6.5 / 10,000.
- This condition is associated with stillbirths and neonatal deaths in 19% of cases. In 1995–98, 13% of reports of this condition were associated with pregnancy termination, probably indicating the presence of other more serious malformations in the fetus.
- A large significant excess of male babies is seen.
- There is no significant association with maternal age.
- The increased prevalence in babies of Asian-born women is approaching significance.
- There are no significant regional variations.

Oesophageal Atresia and/or Stenosis

British Paediatric Association code 750.30–750.38

Occlusion or narrowing of the oesophagus, with or without tracheo-oesphageal fistula.

- The numbers are fluctuating each year with an overall prevalence in recent years of 4.1 / 10,000.
- In recent years, neonatal death occurred in 21% of cases and 8% were stillborn.
- There is a non-significant excess of males with this condition.
- Over 40% of these babies are born weighing between 1000 and 2499 gm. This high proportion of low birth weight babies is not seen for any other birth defect.
- A U-shaped maternal age effect (women aged <20 and >40 years have increased birth prevalence) is apparent, but not significant.
- There are no significant differences for women from different countries of birth nor are there any regional associations.

Anorectal Atresia and/or Stenosis

British Paediatric Association code 751.21–751.24

Imperforate anus or absence or narrowing of the communication between rectum and anus, with or without fistula to neighbouring organs.

- There has been an increase in the overall birth prevalence of this condition from 3.8/1000 births in 1983–1994 to 5.4/1000 in 1995–1998. It is present with another system defect in 57% of cases.
- There is a significant two-fold increased birth prevalence in males.
- There is a significant excess of twins.
- There are no associations with maternal age, country of birth nor region of residence.

Hypospadias

British Paediatric Association code 752.60

Abnormal opening of the male urethra upon the undersurface of the penis.

- There was a marked increase in notifications of hypospadias in 1989. Since 1989 over 150 cases each year reported to the BDR, compared with 100 or so before 1988. Repair of this defect has been done at 6–18 months of age since the mid 1980s, however prior to that time repair was done at 3–4 years of age and notification may not have been made. The earlier management, plus our current system of receiving inpatient listings from the Royal Children's Hospital, may account for more notifications to the BDR in recent years. The birth prevalence for 1995–1998 is 32.1 / 1000.
- As there are few associated perinatal deaths (1.5% in 1995–1998), it is likely hypospadias is rarely associated with major (lethal) malformations. It occurs as an isolated defect in 86% of cases.
- There is no linear trend with maternal age.
- There is significant variation in prevalence with maternal country of birth. Women of Asian background have a significantly reduced risk compared to almost all other ethnic groups of women.
- There are no significant regional variations.

Renal Agenesis and Dysgenesis

British Paediatric Association code 753.00–753.01

Bilateral or unilateral absence of the kidneys or severe dysplasia.

Unilateral disease is very different from bilateral, but the figures here include both conditions.

- There are marked annual fluctuations in numbers of babies with renal agenesis, from over 40 to 20 cases per year. The overall birth prevalence has increased to 6.5 / 1000 in 1995–1998 from 4.8 / 1000 in 1983–1994.
- Some of the marked reduction in neonatal deaths and stillbirths may be due to the more severe cases being identified *in utero* and being represented amongst the increased proportion of terminations. Also, unilateral disease, compatible with life, may be more prevalent and account for the 54% surviving.
- There is a significant two-fold increased birth prevalence in males.
- In the earlier years, many of these babies were low birth weight, but in the recent study years, more than 50% had normal birth weights.
- There is no significant association with maternal age.
- Asian-born women have a significantly lower prevalence of babies with this condition, compared to Australian-born and Middle Eastern-born women.
- The differences in regional variation are not significant.

Cystic Kidney Disease

British Paediatric Association code 753.10–753.18

This covers a wide range of malformations with renal cysts of varying size and extent, occurring bilaterally or unilaterally. Polycystic and multicystic kidney disease are both included.

- There has been a linear increase in overall birth prevalence of babies with this condition, from 4.0 / 1000 in 1983–1994 to 6.5 / 1000 in 1995–1998. The number of liveborn babies that survive at least 28 days has increased from 47% to 64%. This may be due to increased ascertainment of milder cases. There are now over 35 cases reported each year.
- Again there is an excess of males with renal disease, but in this condition, it is not significant.
- There is no significant association with maternal age, country of birth nor region of residence.

Obstructive Defects of Renal Pelvis

British Paediatric Association code 753.20 – 753.29

This heterogeneous group includes hydronephrosis and any other defect that results in dilatation of the renal collecting system, bilaterally or unilaterally.

- Ultrasound in pregnancy has identified a large number of babies with this condition. Where possible, this diagnosis is confirmed postnatally, before inclusion in the BDR. A huge increase was seen in 1994 and again in 1998, when over 210 cases were reported. The overall birth prevalence has increased three-fold from 10.5 / 1000 in 1983–1994 to 28.0 / 1000 in 1995–1998, and, specifically 36.7 / 1000 in 1998.
- There is nearly a 3-fold increased risk for males compared with females. This difference is apparent even when analysing the data year by year. The Table below shows that an excess of males was not caused by recent diagnoses in male babies less than one year of age; males are often investigated for this condition after only one urinary tract infection, while females may have several before such investigation.

Year	Male	Female
1983	11	5
1984	25	7
1985	28	10
1986	27	8
1987	23	12
1988	32	9
1989	35	15
1990	66	18
1991	69	29
1992	61	25
1993	68	27
1994	113	35
1995	101	39
1996	124	38
1997	130	44
1998	**167**	**60**

- In 1995–1998 only 8% died in the perinatal period, suggesting that association with lethal malformations is uncommon.
- Most babies (83.4%) are normal birth weight.
- The higher rate in babies of women aged 40 years and over, compared with all other ages, is not significant.
- Women born in the Middle East have a significantly higher prevalence of babies with this condition, compared to Australian-, UK- , European and Asian-born women.
- There are significantly more births of babies with this condition to women living in Northern Metro region compared to those living in Eastern Metro. Other differences are not significant.

Congenital Dislocation of the Hip

British Paediatric Association code 754.30

The femoral head is displaced (or displaceable) from the acetabulum of the pelvis.

- This is not to be confused with 'clicky hips' which are not included in the BDR.
- This is one of the more commonly reported conditions, the birth prevalence of which has remained at over 150 cases per year since 1983 (except for 1997 when there were 148 cases). There has been a decline in prevalence from 29.4 / 1000 in 1983–1994 to 26.1 / 1000 in 1995–1998.
- There is almost no associated stillbirth or neonatal death.
- Female babies have a four-fold increased risk and a prevalence of 46.0 / 1000 births.
- This condition is very seldom seen in twins.
- This condition is seldom seen in babies weighing less than 2500 gram which suggests that CDH occurs late in pregnancy secondary to reduction in space.
- There are some significant associations with maternal age:
  – There is a reduced risk for women aged 20 –24 years compared to older women up to 40 years
  – There are significantly fewer babies with CDH born to women 40 years and over compared to women 25–34 years.
- A significantly lower birth prevalence of babies with CDH was seen in Oceanic-, Middle Eastern-, Asian-, European-, South American-born women, compared to Australian- and UK-born women.
- Women living in Western Metro and Northern Metro regions have the lowest birth prevalences of babies with CDH and these figures are both significantly lower than those of women from all other regions. Women living in Eastern Metro have significantly fewer babies with this condition than women from Southern Metro and Grampians region (the two regions with the highest prevalence).

Limb Reduction Defects

British Paediatric Association code 755.20–755.49

There is a wide range of severity from partial absence of a phalanx to complete absence of a major skeletal structure such as a whole limb. These may for other purposes be analysed in groups: transverse, longitudinal, intercalary, multiple or unspecified.

- 30–40 cases of limb reduction defects are reported to the BDR per year, except for a peak in 1996 when 60 cases were notified. There are an increasing number of pregnancies terminated when this defect is recognised in a fetus. It is often associated with other malformations as suggested by the figure of approximately 26% dying in the perinatal period.
- There is no excess of one or other sex.
- There is a significantly increased prevalence in twins.
- There are no significant associations with maternal age, country of birth nor region of residence.

Diaphragmatic Hernia

British Paediatric Association code 756.61

Herniation of the abdominal organs into the thorax through a defect in the diaphragm.

- In 1990 and 1991 there was a marked increase in the number of births where this defect was present (primarily stillbirths and terminations). Another marked fluctuation was observed in 1995 when the birth prevalence was 5.3/1000. The overall birth prevalence for 1995–1998 is 4.1/1000 compared to 3.3/1000 for 1983–1994.
- The annual proportion that have been liveborn, but died as neonates, has declined from 39% to 29% in 1995–1998. This may reflect identification of the problem prenatally by ultrasound and preparation for acute management at the time of birth, resulting in better neonatal outcome.
- There is no difference between male and female prevalence.
- The apparent increasing birth prevalence with advancing maternal age is not significant.
- There is no significant maternal country of birth nor regional association.

Exomphalos

British Paediatric Association code 756.70

Herniation of abdominal contents through umbilical insertion and covered by membrane which may or may not remain intact.

- Overall birth prevalence of exomphalos has gradually increased from 2.9 / 1000 to 3.8 / 1000 in 1995–1998, with prevalence in 1998 being 4.7 / 1000. In 1995–1998, there was a termination of pregnancy in 48.5% of cases.
- There is a 13% neonatal death rate, indicating the more severe nature of the condition compared with the other abdominal wall defect, gastroschisis, which has a 4% neonatal death rate.
- There is a significant increased prevalence in twin pregnancies.
- The significantly higher prevalence in women 35 years and older may reflect the association with trisomy 18. In 26% of cases there is a chromosomal abnormality.
- There are no significant associations with maternal country of birth nor region of residence.

Gastroschisis

British Paediatric Association code 756.71

Visceral herniation through an abdominal wall defect, lateral to an intact umbilical cord.

- The increase in reported prevalence of this rare condition in 1992 may have been a chance fluctuation or may have represented a true change. The finding that the 1994 numbers were again low reduced the urgency to investigate this increase. However, from 1995–1997, there was another increase, also reported in other Australian States and overseas.
- There have been small numbers of pregnancy terminations for this condition.
- Small proportions are stillborn (9%) or die in the neonatal period (4%). This is not often associated with a major malformation.
- Many (56%) of these babies are born with birth weight less than 2500 gms.
- There is an inverse association with maternal age, with a significant seven-fold increased prevalence in teenage mothers. A number of international studies are underway to examine this unusually high risk. There have been no cases born to the 15,718 women more than 39 years of age.
- There are no maternal country of birth nor regional associations.

Trisomy 21

British Paediatric Association code 758.00–758.09

Down syndrome—additional chromosome 21.

- This is the most common of the autosomal aneuploidies with an overall prevalence from 1983–1998 of 16.9 / 10,000 (1 in 592). The prevalence in the last four years was 20.8 / 1000.
- The number of reported trisomy 21 pregnancies (terminations plus births) has increased over the 16 years. This is because the proportion of older women (>35 years of age) giving birth has increased and more fetuses are being detected with this condition as a result of more prenatal diagnosis taking place. In addition there is more prenatal detection by maternal serum screening and ultrasound in women of all ages.
- There is a significant excess of males.
- There is no association with twinning.
- The expected association with maternal age is seen. From 1983–1994, 62% of the babies with trisomy 21 were born to women who were less than 35 years of age, but in the last four years (1995–1998), only 44% were identified in younger women. This shift in proportions is probably due to affected fetuses, that would once have spontaneously aborted and never been identified as affected, now being identified by prenatal testing in older women in the first and early second trimester.
- The overall prevalence for women 35–39 years is approximately 1 in 200 and for women 40 years and over it is 1 in 66.
- There is no significant association with mother's country of birth nor region of residence.

Trisomy 13

British Paediatric Association code 758.10–758.19

Patau syndrome—additional chromosome 13

- This is the least common of the autosomal trisomies compatible with life and has a total birth prevalence of 1.7/ 10,000. As with trisomy 21, there has been a marked increase in prevalence in the last four years, compared to the prevalence for 1983–1994, due to an increase in the number of fetuses detected in utero and pregnancies terminated.
- Only 8.8%, or 15 cases in the 16 year period, survived the neonatal period.
- There is no significant difference in male and female prevalence.
- There is the expected trend with advancing maternal age. Women 35 years and older have a significantly increased risk of having a baby with this condition compared with women less than 35 years. For women 40 years and older, the risk of having a baby with this condition is almost the same as that for a 30–34 year old woman having a baby with trisomy 21.
- There are no associations with mother's country of birth nor region of residence.

Trisomy 18

British Paediatric Association code 758.20–758.29

Edward syndrome—additional chromosome 18.

- This trisomy is more than twice as common as trisomy 13 with a birth prevalence of 4.2 / 10,000. The prevalence in the last four years was 6.2 / 10,000, with a marked increase in the number of recognised affected pregnancies and subsequent termination.
- Only 41 cases (9.7%) in the 16 year period survived the neonatal period, or 6% of those born since 1995.
- There is a non-significant excess of females.
- Birth prevalence increased markedly with increasing maternal age. A significant difference is seen for women 30–34 years compared with women 25–29 years and these significant differences are even greater for older women. Women 40 years and older have a risk equivalent to 35–36 year old women having a baby with trisomy 21
- Asian-born women have a significantly increased risk of having a baby with this condition compared to Australian, European and Middle Eastern-born women.
- Women living in Eastern Metropolitan region have an increased risk compared with women living in Loddon Mallee region, almost certainly reflecting maternal age characteristics of the regions. (Refer to Table 2.5 in Births in Victoria, 1996–1998, p.15(6)).

- Except for women aged less than 20, the prevalence of birth defects increases with increasing age.
- Women aged 35+ comprise 15% of all mothers who have a pregnancy affected by a birth defect and have a relative risk of having a child with a malformation of 1.34 compared to younger women (95%CI 1.30–1.38,p<0.0001)
- If all mothers with pregnancies affected by chromosomal abnormalities (Trisomy 21 , Trisomy 18 and Trisomy 13) are excluded, then the proportion of women aged 35 or more is 13.1%, giving a relative risk of having a child with a malformation 1.13 compared to younger women (95% CI 1.10–1.17, p<0.0001)

Total	**32,287**	***100.0***	**998,728**	***100.0***		**314.5**	**321.4**

- The prevalence of birth defects in pregnancies of women identified as Koori in the Perinatal Morbidity Statistics System is significantly less than those identified as non-Koori (RR 0.77, 95% CI 0.66–0.91, p=0.001).

Table 4.5 Birth Defect Cases by Marital Status (excluding TOPs), 1983–1998

Marital Status	No. Cases	%	Total No. Cofinements	%	N/10,000	95% Confidence Interval LL	UL
Single	3,284	*10.2*	90,481	*9.1*	356.98	344.9	369.1
Divorced	179	*0.6*	4,473	*0.4*	391.24	334.4	448.1
Widowed	20	*0.1*	677	*0.1*	295.42	167.9	423.0
Separated	233	*0.7*	6,911	*0.7*	331.36	289.2	373.6
Married	26,489	*82.0*	831,448	*83.3*	313.36	309.6	317.1
De facto	2,018	*6.3*	63,178	*6.3*	314.03	300.4	327.6
Unknown	64	*0.2*	1,560	*0.2*	403.85	306.2	501.5
Total	**32,287**	***100.0***	**998,728**	***100.0***		**314.5**	**321.4**

- If marital status is divided into unpartnered (single, separated, divorced, widowed) versus partnered (defacto, married), there is a statistically significant increased relative risk of 1.59 (95% CI 1.54–1.64, p<0.0001) for unpartnered women.

Table 4.6 Birth Defect Cases by Parity (excluding TOPs), 1983–1998

Parity	No. Cases	%	Total No. Cofinements	%	N/10,000	95% Confidence Interval LL	UL
None	13,530	*41.9*	396,771	*39.7*	341.00	335.4	346.6
One	10,459	*32.4*	341,808	*34.2*	305.99	300.2	311.8
Two	5,238	*16.2*	170,619	*17.1*	307.00	298.8	315.2
Three	1,963	*6.1*	59,846	*6.0*	328.01	313.7	342.3
Four	631	*2.0*	18,115	*1.8*	348.33	321.6	375.0
Five or more	461	*1.4*	11,508	*1.2*	400.59	364.8	436.4
Unknown	5	*0.0*	61	*0.0*	819.67	131.3	1508.1
Total	**32,287**	***100.0***	**998,728**	**100.0**	**323.28**	**319.8**	**326.8**

- Primiparous women are more likely to have babies with birth defects than multiparous women (RR 1.09, 95% CI 1.07,1.12, p<0.0001).

5. Birth Defect Cases by Selected Infant Characteristics

Table 5.1 Birth Defect Cases by Number of Defects per Case 1983–1998

Number	No. Cases	%
1	13,949	40.0
2	8996	25.8
3	4575	13.1
4+	7327	21.0
Total	**34,847**	**100.0**

- 34,847 birth defect cases were notified to the BDR, comprising 55,743 individual birth defects
- 40% of cases had an isolated defect.
- The high proportion of cases with multiple defects (ie. 60%) is increased by our coding practice of classifying each manifestation of a syndrome separately.

Table 5.2 Birth Defect Cases by Infant Gender, 1983–1998

Sex	No. Cases	%	Total No. Cofinements	%	N/10,000	95% Confidence Interval LL	UL
Male	19,182	*55.0*	521,553	*51.4*	367.8	362.7	394.4
Female	14,910	*42.8*	492,558	*48.5*	302.7	297.9	330.2
Indeterminate	300	*0.9*	298	*0.0*			
Unknown	455	*1.3*	454	*0.0*			
Total	**34,847**	***100.0***	**1,014,863**	***100.0***			

- Birth defects were more commonly reported in males than in females (ie 3.7% of all male pregnancies versus 3.0% of all female pregnancies). This gives a relative risk of having a birth defect for males of 1.21 (95% CI 1.19–1.24, p<0.0001).
- There were 300 cases of indeterminate sex. All births of indeterminate sex are considered to be birth defects.

Table 5.3 Birth Defect Cases by Birthweight (excluding TOPs) , 1983–1998

Birthweight Group	No. Cases	%	Total No. Cofinements	%	N/10,000	95% Confidence Interval LL	UL
<1000	1,560	*4.8*	6,748	*0.7*	2,311.8	2,211.2	2,521.0
1000–2499	4,747	*14.6*	54,688	*5.4*	868.0	844.4	948.1
2500 +	25,772	*79.4*	949,958	*93.8*	271.3	268.0	291.1
Unknown	366	*1.1*	1,067	*0.1*	3,430.2	3,145.3	3,916.5
Total	**32,445**	***100.0***	**1,012,461**	***100.0***	**320.5**	**317.0**	**339.6**

- Malformations were recorded among 10.3% of low birthweight infants (<2500 grams) compared with 2.7 % of infants with birthweights of 2500 grams or more.

Table 5.4 Birth Defect Cases by Gestational Age (excluding TOPs), 1983–1998

Gestation (weeks)	No. Cases	%	Total No Cofinements	%	N/10,000	95% Confidence Interval LL	UL
20–27	1,579	*4.9*	6,565	*0.6*	2,405.2	2,301.8	2,616.0
28–31	1,183	*3.6*	7,317	*0.7*	1,616.8	1,532.4	1,826.6
32–36	3,449	*10.6*	53,972	*5.3*	639.0	618.4	720.7
37–41	24,897	*76.7*	902,898	*89.2*	275.7	272.4	296.1
> 41	1046	*3.2*	35,900	*3.5*	291.4	274.0	393.3
Unknown	291	*0.9*	5809	*0.6*	500.9	444.8	751.6
Total	**32,445**	***100.0***	**1,012,461**	***100.0***	**320.5**	**317.0**	**339.6**

- 9.2% of premature infants (< 37 weeks) had a malformation compared to 2.8% among term and post-term infants (>= 37 weeks).

Table 5.5 Birth Defect Cases by Plurality, 1983–1998

Plurality	No. Cases	%	Total No. Cofinements	%	N/10,000	95% Confidence Interval LL	UL
Single	33,410	*95.9*	987,675	*97.3*	338.3	334.7	357.7
Twin	1,353	*3.9*	26,192	*2.6*	516.6	489.8	634.5
Triplet	69	*0.2*	939	*0.1*	734.8	567.9	1,350.5
Quad	6	*0.0*	48	*0.0*	1,250.0	314.4	3,896.3
Unknown	9	*0.0*	9	*0.0*	10,000.0	10,000.0	10,000.0
Total	**34,847**	***100.0***	**1,014,863**	*100.0*	**343.4**	**339.8**	**362.5**

- 3.4% of singleton births had a birth defect.
- 5.3% of multiple births (twins, triplets, quads) had a birth defect.
- Relative risk for multiple versus singleton birth is 1.55 (95% CI 1.48–1.64,p <0.0001).

Table 5.6 Birth Defect Cases by Rank (multiple pregnancies only), 1983–1998

Rank	No. Cases	%	Total No. Cofinements	%	N/10,000	95% Confidence Interval LL	UL
1	715	*50.1*	13,415	*49.4*	533.0	495.0	697.6
2	677	*47.4*	13,414	*49.4*	504.7	467.7	669.6
3	21	*1.5*	325	*1.2*	646.2	378.9	1,697.7
4	2	*0.1*	12	*0.0*	1,666.7		
Unknown	13	*0.9*	13	*0.0*			
Total	**1,428**	***100.0***	**27,179**	***100.0***		**498.9**	**641.1**

- Within the multiple births, 715 (50.1%) were the first born and 677 (47.4%) were second born infants.

Table 5.7 Perinatal Mortality Associated with Birth Defect Cases (excluding TOPs), 1983–1998

Status	No. Cases	%	Total No. Cofinements	%	N/10,000	95% Confidence Interval LL	UL
Liveborn, surviving >28 days	29,032	*89.5*	1,000,776	*98.8*	290.1	286.8	309.4
Stillborn	1,553	*4.8*	7,397	*0.7*	2,099.5	2,006.7	2,302.1
NND	1,860	*5.7*	4,288	*0.4*	4,337.7	4,189.3	4,562.9
Total	**32,445**	***100.0***	**1,012,461**	***100.0***	**320.5**	**317.0**	**339.6**

1. Perinatal mortality is high among infants with birth defects.
- 1,553 (4.8%) infants were stillborn and 1,860 (5.7%) were neonatal deaths. This corresponds to a perinatal mortality rate of 105.2 / 1,000 births with a malformation.
- These mortality figures comprise all birth defect cases, including those where the cause of death may not be directly related to the birth defect.
- Relative risk of a perinatal death for a baby with a malformation compared to a baby without a malformation is 13.81 (95% CI 13.25,14.40,$p < 0.0001$).

2. Birth defects are a major contributor to perinatal mortality.
- Between 1983–1998 there were the 7,397 stillbirths, 1,553 (21%) had a birth defect.
- Between 1983–1998 there were 4,288 neonatal deaths, 1,860 (43.4%) had a birth defect.
- 29.2% of all perinatal deaths were associated with one or more birth defects.

Appendix A: List of Exclusions

NB: There has been some variation in this list of exclusions between 1983–1998. Some excluded conditions may be included in this report if they were previously not excluded AND occur with other birth defects

Abnormal palmar creases

Accessory nipples

Anal fissure

Balanced autosomal translocation (unless ocurring with structural defects)

Birth injuries

Birth marks (smaller than 4cm, not including giant naevus)

Bowing of legs (unless severe)

Blocked tear ducts (dacrostenosis)

Brushfield spots

Cephalhaematoma

Cleft gum

Clicky hips

Clinodactyly

Craniotabes (unless severe)

Dermatogplyphic abnormalities

Ear abnormalities (minor)

Epicanthic folds

Gastro-oesophageal reflux

Haemangioma (<4 cm wide)

Hernia—inguinal, umbilical

High-arched palate

Hydrocoele

Hypertelorism

Imperforate hymen

Laryngeal stridor

Larygomalacia

Low slung / set ears

Macroglossia (large tongue)

Meckel's diverticulum

Meconium ileus

Mental retardations (unless occurring with a syndrome / structural defect)

Metatarsus varus

Micrognathia (unless severe)

Mongolian spots

Occiput, flat / prominent

Patent ductus arteriosus (< 37 weeks)

Philtrum, long / short

Plagiocephaly

Pre-auricular sinus

Prominent forehead

Protruding tongue

Ptosis

Pyloris stenosis

Retrognathia (unless severe)

Rocker-bottom feet (prominent heels)

Sacral pits, dimples, sinuses

Short sternum

Simian creases

Single umbilical artery / 2 vessels in cord

Skin folds / tags

Slanting eyes

Small mouth

Spina bifida occulta

Sternomastoid tumour

Subluxating knee joint

Talipes (positional)

Toe anomalies—minor

Tongue tie

Torticollis

Ureteric reflux (ultrasound diagnosed)

Webbing of 2nd & 3rd toes / fingers

Wide suture lines

Appendix B: Routine Data Items Contained in the Birth Defects/Congenital Malformations Register

Maternal data:	postcode, date of birth, method of prenatal diagnosis, name
Infant /fetus data:	hospital of birth, date of birth (or termination), sex, birthweight, plurality, rank, discharge status, date of death (if applicable), BPA Codes for congenital malformations, position code, source of notification

Other data items available from linkage to the Perinatal Morbidity Statistics Form:

(1) Maternal items:	UR number, local government area, region, country of birth, aboriginality, discharge date and status, marital status, number of previous pregnancies, date of completion of last pregnancy, outcome of last pregnancy, maternal medical conditions, obstetric°complications, indication(s) for operative delivery, complications of labour birth and postnatal, procedures and operations, type of labour, presentation, method of delivery
(2) infant data items:	apgar, time to establish respiration, resuscitation methods, neonatal morbidity
